

CDA6530: Performance Models of Computers and Networks (Fall 2010)

Project 1: Random Variables Simulation and Analysis

(assigned Oct. 5th; submit by Oct. 17th midnight with 10 points bonus;
submission deadline is Oct. 21st midnight)

In this project, you will generate different random variables, and then compare your simulation results with analytical results. Everything should be done in Matlab platform in order for you to learn using this useful tool.

Note that you are required to NOT use any statistical functions provided by Matlab and its toolbox. You should use what I introduced in class lecture to generate random variables (the inverse transform method or polar method), and you need to calculate distribution by your own code. You should ONLY use the basic Matlab operations and matrix/vector operations. When drawing figures, you should only use plot() function. Using Matlab's statistical functions will be treated as not completing the assignment!

What to submit: Submit a report with all required figures and comparison tables. In addition, submit your matlab code (.m files). You can put all files in a .zip file to submit in webcourse.

1. Generate 1000 samples for each of the following discrete random variables:

- (a). Binomial distribution with $n=40$, $p=0.7$, and distr. with $n=50$, $p=0.5$
- (b). Geometric distribution with $p=0.5$ and distr. with $p=0.3$
- (c). Poisson distribution with $\lambda = 6$ and $\lambda = 4.5$

For each class of the above distribution, plot probability mass function for each set parameters on one figure (you should have two curves on each figure). In addition, you should also plot the corresponding analytical results (probability mass function curve based on distribution formulas) on the same figure. In this way, you can verify whether your simulated random variables match with analytical results.

That means on each figure, there are four curves (two simulations, two analytical). Use "legend" to denote each curve, and use different line style and color for each curve.

You should show the X-axis with reasonable range such that the curves can be clearly seen (check wikipedia's figures for these distributions).

In addition, calculate the mean value and variance of generated samples for each distribution (sample mean and sample variance). Compare the results with the analytical results.

2. Generate 1000 samples for each of the following continuous random variables:

- (a). Exponential distribution with $\lambda = 1.2$ and $\lambda = 2.1$
- (b). Normal distribution with $\mu = 3.1, \sigma^2 = 5$ and $\mu = 1, \sigma^2 = 2$

For each class of the above distribution, plot the cumulative distribution function for each set parameters on one figure (you should have two curves on each figure). In addition, you should also plot the corresponding analytical results (CDF curve based on distribution formulas) on the same figure. In this way, you can verify whether your simulated random variables match with analytical results.

In addition, calculate the mean value and variance of generated samples for each distribution (sample mean and sample variance). Compare the results with the analytical results.
